# Diffing Mutually Recursive Types

Victor Cacciari Miraldo University of Utrecht

December 10, 2016

# 1 Our Universe

The universe we are using is a Sums-of-Products over type variables and constant types.

```
\begin{array}{ll} \mathsf{data} \ \mathsf{Atom} \ (n: \mathbb{N}) : \mathsf{Set} \ \mathsf{where} \\ \mathsf{I} : \mathsf{Fin} \ n & \to \mathsf{Atom} \ n \\ \mathsf{K} : \mathsf{Fin} \ ks\# & \to \mathsf{Atom} \ n \end{array}
```

Constructor I refers to the n-th type variable whereas K refers to a constant type. Value ks# is passed as a module parameter. We denote products by  $\pi$  and sums by  $\sigma$ , but they are just lists.

```
\pi: \mathbb{N} \to \mathsf{Set}
\pi = \mathsf{List} \circ \mathsf{Atom}
\sigma\pi: \mathbb{N} \to \mathsf{Set}
\sigma\pi = \mathsf{List} \circ \pi
```

 $\mathsf{Parms}:\, \mathbb{N} \to \mathsf{Set}_1$ 

Interpreting these codes is very simple. Here, Parms is a valuation for the type variables.

Note that here, Parms n really is isomorphic to n types that serve as the parameters to the functor  $\lceil F \rceil$ . When we introduce a fixpoint combinator, these parameters are

used to to tie the recursion knot, just like a simple fixpoint:  $\mu F \equiv F(\mu F)$ . In fact, a mutually recursive family can be easily encoded in this setting. All we need is n types that refer to n type-variables each!

This universe is enough to model Context-Free grammars, and hence, provides the basic bare bones for diffing elements of an arbitrary programming language. In the future, it could be interesting to see what kind of diffing functionality indexed functors could provide, as these could have scoping rules and other advanced features built into them.

# 1.1 SoP peculiarities

One slightly cumbersome problem we have to circumvent is that the codes for type variables and constant types have a different *type* than the codes for types. This requires more discipline to organize our code. Nevertheless, we may wish to see Atoms as a trivial Sum-of-Product.

```
\begin{array}{l} \alpha \,:\, \{n:\, \mathbb{N}\} \,\to\, \mathsf{Atom}\,\; n \to \sigma\pi \,\; n \\ \alpha \,\: a = (a::\, [])::\, [] \end{array}
```

Instead of having binary injections into coproducts, like we would on a regular-like universe, we have n-ary injections, or, constructors. We encapsulate the idea of constructors of a  $\sigma\pi$  into a type and write a view type that allows us to look at an inhabitant of a sum of products as a constructor and data.

First, we define constructors:

```
\begin{array}{l} \mathsf{cons\#}: \{n: \mathbb{N}\} \to \sigma\pi \ n \to \mathbb{N} \\ \mathsf{cons\#} = \mathsf{length} \\ \\ \mathsf{Constr}: \{n: \mathbb{N}\} (ty: \sigma\pi \ n) \to \mathsf{Set} \\ \mathsf{Constr} \ ty = \mathsf{Fin} \ (\mathsf{cons\#} \ ty) \end{array}
```

Now, a constructor of type C expects some arguments to be able to make an element of type C. This is a product, we call it the typeOf the constructor.

```
\begin{array}{l} \mathsf{typeOf}: \{n: \mathbb{N}\}(ty: \sigma\pi\ n) \to \mathsf{Constr}\ ty \to \pi\ n \\ \mathsf{typeOf}\ []\ () \\ \mathsf{typeOf}\ (x:: ty)\ \mathsf{fz}\ = x \\ \mathsf{typeOf}\ (x:: ty)\ (\mathsf{fs}\ c) = \mathsf{typeOf}\ ty\ c \end{array}
```

Injecting is fairly simple.

```
\begin{split} & \text{inject} : \{n : \mathbb{N}\} \{A : \mathsf{Parms} \ n\} \{ty : \sigma \pi \ n\} \\ & \to (i : \mathsf{Constr} \ ty) \to [\![ \ \mathsf{typeOf} \ ty \ i \ ]\!]_p \ A \\ & \to [\![ \ ty \ ]\!] \ A \\ & \text{inject} \ \{ty = [\!]\!] \ () \ cs \\ & \text{inject} \ \{ty = x :: ty\} \ \mathsf{fz} \ cs \ = \mathsf{i1} \ cs \\ & \text{inject} \ \{ty = x :: ty\} \ (\mathsf{fs} \ i) \ cs \ = \mathsf{i2} \ (\mathsf{inject} \ i \ cs) \end{split}
```

We finish off with a view of  $[ty]_A$  as a constructor and some data. This greatly simplify the algorithms later on.

```
data SOP \{n: \mathbb{N}\}\{A: \mathsf{Parms}\ n\}\{ty: \sigma\pi\ n\}: \llbracket\ ty\ \rrbracket\ A \to \mathsf{Set}\ \mathsf{where} strip : (i: \mathsf{Constr}\ ty)(ls: \llbracket\ \mathsf{typeOf}\ ty\ i\ \rrbracket_p\ A) \to \mathsf{SOP}\ (\mathsf{inject}\ i\ ls)
```

# 1.2 Agda Details

Here we clarify some Agda specific details that are agnostic to the big picture. This can be safely skipped on a first iteration.

As we mentioned above, our codes represent functors on n variables. Obviously, to program with them, we need to apply these to something. The denotation receives a function  $\operatorname{\mathsf{Fin}} n \to \operatorname{\mathsf{Set}}$ , denoted  $\operatorname{\mathsf{Parms}} n$ , which can be seen as a valuation for each type variable

In the following sections, we will be dealing with values of  $[ty]_A$  for some class of valuations A, though. We need to have decidable equality for A k and some mapping from A k to  $\mathbb N$  for all k. We call such valuations a well-behaved parameter:

```
record WBParms \{n: \mathbb{N}\}(A: \mathsf{Parms}\ n): \mathsf{Set}\ \mathsf{where} constructor wb-parms field \mathsf{parm\text{-}size}: \ \forall \{k\} \to A\ k \to \mathbb{N} \mathsf{parm\text{-}cmp}: \ \forall \{k\}(x\ y: A\ k) \to \mathsf{Dec}\ (x \equiv y)
```

## TODO

The field parm-size is not really needed anymore! Remove it!

The following sections discuss functionality that does not depend on parameters to codes. Hence, we will be passing them as Agda module parameters. We also set up a number of synonyms to already fix the aforementioned parameter. The first diffing technique we discuss is the trivial diff. It's module is declared as follows:

```
\begin{array}{l} \textbf{module} \ \ \mathsf{RegDiff.Diff.Trivial.Base} \\ \{\mathit{ks\#} \ : \ \mathbb{N}\}(\mathit{ks} : \ \mathsf{Vec} \ \mathsf{Set} \ \mathit{ks\#})(\mathit{keqs} : \ \mathsf{Vecl} \ \mathsf{Eq} \ \mathit{ks}) \\ \{\mathit{parms\#} : \ \mathbb{N}\}(A : \mathsf{Parms} \ \mathit{parms\#})(\mathit{WBA} \ : \ \mathsf{WBParms} \ \mathit{A}) \\ \textbf{where} \end{array}
```

We stick to this nomenclature throughout the code. The first line handles constant types: ks# is how many constant types we have, ks is the vector of such types and keqs is an indexed vector with a proof of decidable equality over such types. The second line handles type parameters: parms# is how many type-variables our codes will have, A is the valuation we are using and WBA is a proof that A is  $well\ behaved$ .

#### **TODO**

Now parameters are setoids, we can drop out the WBA record.

Below are the synonyms we use for the rest of the code:

```
U:\mathsf{Set}
U = \sigma \pi \ parms \#
Atom: Set
\mathsf{Atom} = \mathsf{Atom}' \; parms \#
\Pi : Set
\Pi = \pi \ parms\#
\mathsf{sized} \,:\, \{\, p \,:\, \mathsf{Fin} \,\, parms\#\} \,\to\, A \,\, p \,\to\, \mathbb{N}
sized = parm-size WBA
\_\stackrel{?}{=} \mathsf{-A}\_: \{p: \mathsf{Fin}\ parms\#\}(x\ y:\ A\ p) \to \mathsf{Dec}\ (x \equiv y)
\stackrel{?}{=}-A = parm-cmp WBA
\llbracket \_ \rrbracket_a : \mathsf{Atom} \to \mathsf{Set}
[\![ a ]\!]_a = interp_a \ a \ A
[\![\underline{\phantom{a}}]\!]_p:\Pi\to\mathsf{Set}
[\![ p \ ]\!]_p = \mathsf{interp}_p \ p \ A
\llbracket \_ \rrbracket : \mathsf{U} \to \mathsf{Set}
\llbracket u \rrbracket = \mathsf{interp}_s \ u \ A
UUSet: Set<sub>1</sub>
UUSet = U \rightarrow U \rightarrow Set
AASet: Set<sub>1</sub>
\mathsf{AASet} = \mathsf{Atom} \to \mathsf{Atom} \to \mathsf{Set}
ППSet : Set<sub>1</sub>
\Pi\Pi\mathsf{Set}=\Pi\to\Pi\to\mathsf{Set}
contr : \forall \{a \ b\} \{A : \mathsf{Set} \ a\} \{B : \mathsf{Set} \ b\}

ightarrow (A 
ightarrow A 
ightarrow B) 
ightarrow A 
ightarrow B
\mathsf{contr}\ p\ x = p\ x\ x
UU \rightarrow AA : UUSet \rightarrow AASet
UU \rightarrow AA P a a' = P (\alpha a) (\alpha a')
\rightarrow\!\!\alpha: \{a: \mathsf{Atom}\} \rightarrow \llbracket \ a \ \rrbracket_a \rightarrow \llbracket \ \alpha \ a \ \rrbracket
\rightarrow \alpha \ k = i1 \ (k \ , unit)
```

# 2 Computing and Representing Patches

Intuitively, a Patch is some description of a transformation. Setting the stage, let A and B be a types, x:A and y:B elements of such types. A patch between x and y must

specify a few parts:

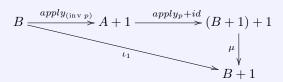

- i) An  $apply_p: A \to Maybe\ B$  function,
- ii) such that  $apply_p \ x \equiv \text{just } y$ .

Well,  $apply_p$  can be seen as a functional relation (R is functional iff  $img \ R \subseteq id$ ) from A to B. We call this the "application" relation of the patch, and we will denote it by  $p^{\flat} \subseteq A \times B$ .

### Needs discussion:

There is still a lot that could be said about this. I feel like  $p^{\flat}$  should also be invertible in the sense that:

- i) Let (inv p) denote the inverse patch of p, which is a patch from B to A.
- ii) Then,  $p^{\flat} \cdot (\text{inv } p)^{\flat} \subseteq id$  and  $(\text{inv } p)^{\flat} \cdot p^{\flat} \subseteq id$ , Assuming  $(\text{inv } p)^{\flat}$  is also functional, we can use the maybe monad to represent these relations in **Set**. Writing the first equation on a diagram in **Set**, using the apply functions:

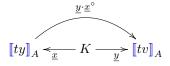

iii) This is hard to play ball with. We want to say, in a way, that  $x(p^{\flat})$  y iff  $y((\text{inv }p)^{\flat})$  x. That is, (inv p) is the actual inverse of p. Using relations, one could then say that  $(\text{inv }p)^{\flat}$  is the converse of  $(p^{\flat})$ . That is:  $(\text{inv }p)^{\flat} \equiv (p^{\flat})^{\circ}$ . But, if  $(\text{inv }p)^{\flat}$  is functional, so is  $(p^{\flat})^{\circ}$ . This is the same as saying that  $p^{\flat}$  is entire! If  $p^{\flat}$  is functional and entire, it is a function (and hence, total!). And that is not true.

Now, let us discuss some code and build some intuition for what is what in the above schema. We will present different parts of the code, how do they relate to this relational view and give examples here and there!

#### 2.1 Trivial Diff

The simplest possible way to describe a transformation is to say what is the source and what is the destination of such transformation. This can be accomplished by the Diagonal functor,  $\Delta$ , just fine.

Now, take an element (x, y):  $\Delta ty tv$ . The "application" relation it defines is trivial:  $\{(x, y)\}$ , or, in PF style:

Where, for any  $A, B \in Set$  and  $x : A, \underline{x} \subseteq A \times B$  represents the everywhere x relation, defined by

$$\underline{x} = \{(x, b) \mid b \in B\}$$

This is a horrible patch however: We can't calculate with it because we don't know anything about how x changed into y. Note, however, that  $(x, y)^{\flat} \equiv \underline{y} \cdot \underline{x}^{\circ}$  is trivially functional.

#### Needs discussion:

In the code, we actually define the "application" relation of  $\Delta$  as:

$$(x, x)^{\flat} = id$$
  
 $(x, y)^{\flat} = y \cdot \underline{x}^{\circ}$ 

This suggests that copies might be better off being handled by the trivial diff. We will return to this discussion in section 3

#### 2.1.1 Trivial Diff, in Agda

We will be using  $\Delta$  ty tv for the three levels of our universe: atoms, products and sums. We distinguish between the different  $\Delta$ 's with subscripts a, p and s respectively. They only differ in type. The treatment they receive in the code is exactly the same! Below is how they are defined:

```
\begin{array}{l} \mathsf{delta} \,:\, \forall \{a\} \{A : \mathsf{Set}\ a\} (P : A \to \mathsf{Set}) \\ \to A \to A \to \mathsf{Set} \\ \mathsf{delta}\ P\ a_1\ a_2 = P\ a_1 \times P\ a_2 \end{array}
```

Hence, we define  $\Delta_x = \mathsf{delta} \, \llbracket \cdot \rrbracket_{\mathsf{x}}$ , for  $x \in \{a, p, s\}$ .

# 2.2 Spines

We can make the trivial diff better by identifying whether or not x and y agree on something! In fact, we will aggresively look for copying oportunities. We start by checking if x and y are, in fact, equal. If they are, we say that the patch that transforms x into y is copy. If they are not equal, they might have the same constructor. If they do, the say that the constructor is copied and we put the data side by side (zip). Otherwise, there is nothing we can do on this phase and we just return  $\Delta x$ .

Note that the *spine* forces x and y to be of the same type! In practice, we are only interested in diffing elements of the same language. It does not make sense to diff a C source file against a Haskell source file.

Nevertheless, we define an S structure to capture this longest common prefix of x and y; which, for the SoP universe is very easy to state.

```
\begin{array}{l} \operatorname{\sf data} {\sf S} \ (P : {\sf UUSet}) : {\sf U} \to {\sf Set \ where} \\ {\sf SX} \ : \{ty : {\sf U}\} \to P \ ty \ ty \to {\sf S} \ P \ ty \\ {\sf Scp} \ : \{ty : {\sf U}\} \to {\sf S} \ P \ ty \\ {\sf Scns} : \{ty : {\sf U}\}(i : {\sf Constr} \ ty) \\ \to {\sf ListI} \ ({\sf contr} \ P \circ \alpha) \ ({\sf typeOf} \ ty \ i) \\ \to {\sf S} \ P \ ty \end{array}
```

Remember that contr P x = P x x and  $\alpha : \text{Atom } n \to \sigma \pi n$ ; Here, Listl P l is an indexed list where the elements have type  $P l_i$ , for every  $l_i \in l$ . We will treat this type like an ordinary list for the remainder of this document.

Note that  $\mathsf{S}$  makes a functor (actually, a free monad!) on P, and hence, we can map over it:

```
\begin{array}{lll} \mathsf{S-map} &:& \{ty: \, \mathsf{U}\} \\ && \{P \,\, Q: \, \mathsf{UUSet}\}(X: \, \forall \{k \,\, v\} \, \rightarrow P \,\, k \,\, v \rightarrow \, Q \,\, k \,\, v) \\ && \rightarrow \mathsf{S} \,\, P \,\, ty \rightarrow \mathsf{S} \,\, Q \,\, ty \\ \mathsf{S-map} \,\, f \,(\mathsf{SX} \,\, x) &&= \mathsf{SX} \,\, (f \, x) \\ \mathsf{S-map} \,\, f \,\mathsf{Scp} &&= \mathsf{Scp} \\ \mathsf{S-map} \,\, f \,(\mathsf{Scns} \,\, i \,\, xs) &&= \mathsf{Scns} \,\, i \,\, (\mathsf{map}_i \,\, f \,\, xs) \end{array}
```

Computing a spine is easy, first we check whether or not x and y are equal. If they are, we are done. If not, we look at x and y as true sums of products and check if their constructors are equal, if they are, we zip the data together. If they are not, we zip x and y together and give up.

The "application" relations specified by a spine  $s = \text{spine } x \ y$ , denoted  $s^{\flat}$  are defined by:

$$\begin{aligned} \operatorname{Scp}^{\flat} = & A & \longleftarrow & id \\ & (\operatorname{SX} \, p)^{\flat} = & A & \longleftarrow & P^{\flat} \\ & A & \longleftarrow & A \end{aligned}$$
 
$$(\operatorname{Scns} \, i \, [s1 \, , \, \cdots \, , \, sN])^{\flat} = & \coprod_{k} \Pi_{j} A_{kj} \overset{\operatorname{inj}_{i} \cdot (s_{1}^{\flat} \times \cdots \times s_{n}^{\flat}) \cdot \operatorname{inj}_{i}^{\circ}}{\longleftrightarrow} \coprod_{k} \Pi_{j} A_{kj}$$

where  $\operatorname{inj}_i$  is the injection, with constructor i, into  $\coprod_k T_k$ . It corresponds to the relational lifting of function injection.

Note that, in the (SX p) case, we simply ask for the "application" relation of p. The algorithm produces a S  $\Delta_s$ , so we have pairs on the leaves of the spine. In fact, either we have only one leave or we have  $arity\ C_i$  leaves, where  $C_i$  is the common constructor of x and y in spine x y.

For a running example, let's consider a datatype defined by:

```
2-3-TREE-F : \sigma\pi 1
2-3-TREE-F = []
\oplus (K kN) \otimes I \otimes I \otimes []
\oplus (K kN) \otimes I \otimes I \otimes I \otimes []
\oplus []
```

We ommit the fz for the I parts, as we only have one type variable. We also use  $\_\oplus\_$  and  $\_\otimes\_$  as aliases for  $\_::\_$  with different precedences. As expected, there are three constructors:

```
2-node' 3-node' nil' : Constr 2-3-TREE-F
nil' = fz
2-node' = fs fz
3-node' = fs (fs fz)
```

We can then consider a few spines over [2-3-TREE-F]<sub>Unit</sub> to illustrate the algorithm:

In the case where the spine is  $\mathsf{Scp}$  or  $\mathsf{Scns}\ i$  there is nothing left to be done and we have the best possible diff. Note that on the  $\mathsf{Scns}\ i$  case we do not allow for rearanging of the parameters of the constructor i.

In the case where the spine is SX, we can do a better job! We can record which constructor changed into which and try to reconcile the data from both the best we can. Going one step at a time, let's first change one constructor into the other.

It is important to note that if the output of spine is a SX, then the constructors are different.

#### 2.3 Constructor Changes

Let's take an example where the spine can not copy anything:

```
s = \text{spine} (2\text{-node}' 10 \text{ unit unit}) (3\text{-node}' 10 \text{ unit unit unit})
= SX (2-node' 10 unit unit, 3-node' 10 unit unit)
```

Here, we wish to say that we changed a 2-node into a 3-node. But we are then left with a problem about what to do with the data inside the 2-node and 3-node; this is where the notion of alignment will be in the picture. For now, we abstract it away by the means of a parameter, just like we did with the S. This time, however, we need something that receives products as inputs.

```
\begin{array}{l} \mathsf{data} \ \mathsf{C} \ (P: \Pi\Pi \mathsf{Set}) : \mathsf{U} \to \mathsf{U} \to \mathsf{Set} \ \mathsf{where} \\ \mathsf{CX} \ : \{ ty \ tv : \ \mathsf{U} \} \\ \ \to (i: \mathsf{Constr} \ ty)(j: \mathsf{Constr} \ tv) \\ \ \to P \ (\mathsf{typeOf} \ ty \ i) \ (\mathsf{typeOf} \ tv \ j) \\ \ \to \mathsf{C} \ P \ ty \ tv \end{array}
```

Note that C also makes up a functor, and hence can be mapped over:

```
 \begin{array}{l} \mathsf{C\text{-}map} \; : \; \{ty \; tv : \, \mathsf{U}\} \\ \qquad \qquad \{P \; Q : \Pi\Pi\mathsf{Set}\}(X : \forall \{k \; v\} \to P \; k \; v \to Q \; k \; v) \\ \qquad \to \mathsf{C} \; P \; ty \; tv \to \mathsf{C} \; Q \; ty \; tv \\ \mathsf{C\text{-}map} \; f \; (\mathsf{CX} \; i \; j \; x) = \mathsf{CX} \; i \; j \; (f \; x) \end{array}
```

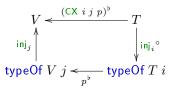

Computing an inhabitant of C is trivial:

```
\begin{array}{l} {\sf change}: \{ty \; tv : \mathsf{U}\} \to \llbracket \; ty \; \rrbracket \to \llbracket \; tv \; \rrbracket \to \mathsf{C} \; \Delta_p \; ty \; tv \\ {\sf change} \; x \; y \; {\sf with} \; {\sf sop} \; x \; | \; {\sf sop} \; y \\ {\sf change} \; \_ \; | \; {\sf strip} \; cx \; dx \; | \; {\sf strip} \; cy \; dy = \mathsf{CX} \; cx \; cy \; (dx \; , \; dy) \end{array}
```

Now that we can compute change of constructors, we can refine our s above. We can compute S-map change s and we will have:

```
\begin{split} c &= \mathsf{S-map\ change}\ s \\ &= \mathsf{SX\ (CX\ 2-node'\ 3-node'\ ((10\ ,\ \mathsf{unit}\ ,\ \mathsf{unit})\ ,\ (10\ ,\ \mathsf{unit}\ ,\ \mathsf{unit}\ ,\ \mathsf{unit}\ )))} \end{split}
```

The "application" relation induced by C is trivial. We just need to pattern match, change the data of the constructor in whatever way we need, then inject into another type.

Note that up until now, everything was deterministic! This is something we are bound to lose when talking about alignment.

# 2.4 Aligning Everything

On the literature for version control system, the alignment problem is the problem of mapping two strings  $l_1$  and  $l_2$  in  $\mathcal{L}$  into  $\mathcal{L} \cup \{-\}$ , for  $\{-\} \not\subseteq \mathcal{L}$  such that the resulting strings  $l'_1$  and  $l'_2$  are of the same length such that for all i, it must not be happen that  $l'_1[i] = - = l'_2[i]$ . For example, Take strings  $l_1 = "CGTCG"$  and  $l_2 = "GATAGT"$ , then, the following is an (optimal) alignment:

Let  $\mathcal{DNA} = \{A, T, C, G\}$ . Finding the table above is the same as finding a partial map:

$$f: \mathcal{DNA}^5 \to \mathcal{DNA}^6$$

such that f(C, G, T, C, G) = (G, A, T, A, G, T). There are many ways of defining such a map. We would like, however, that our definition have a maximal domain, that is, we impose the least possible amount of restrictions. In this case, we can actually define f with some pattern matching as:

$$\begin{array}{ll} f & (C,x,y,C,z) & = (x,A,y,A,z,T) \\ f & \_ & = \text{undefined} \end{array}$$

And it is easy to verify that, in fact, f(C, G, T, C, G) = (G, A, T, A, G, T). Moreover, this is the *maximal* such f that still (provably) assigns the correct destination to the correct source.

On our running example, the leaf of c has type  $\Delta_p$  (typeOf 2-node') (typeOf 3-node'), and it's value is ((10, unit, unit), (10, unit, unit, unit)). Note that we are now dealing with products of different arity. This step will let us say how to align one with the other!

On our example, as long as we align the 10 with the 10, the rest does not matter. One optimal alignment could be:

```
10 — unit unit
10 unit unit unit
```

#### 2.4.1 Back to Agda

We will look at alignments from the "finding a map between products" perspective. Here is where our design space starts to grow, and so, we should start making some distinctios:

- We want to allow sharing. This means that the there can be more than one variable in the defining pattern of our f.
- We do *not* allow permutations, as the search space would be too big. This means that the variables appear in the right-hand side of f in the same order as they appear in the left-hand-side.
- We do *not* allow contractions nor weakenings. That is, every variable on the left-hand-side of f must appear *exactly* once on the right-hand-side.

The following datatype describe such maps:

Note that the indexes of AI, although represented as lists are, in fact, products. Well, turns out that lists and products are not so different after all. Let us represent the f we devised on the  $\mathcal{DNA}$  example using AI. Recall f(C, x, y, C, z) = (x, A, y, A, z, T).

```
f \equiv \mathsf{Ap1}\ C\ (\mathsf{AX}\ \mathsf{Scp}\ (\mathsf{Ap1}^\circ\ A\ (\mathsf{AX}\ \mathsf{Scp}\ (\mathsf{AX}\ (C\ ,A)\ (\mathsf{AX}\ \mathsf{Scp}\ (\mathsf{Ap1}^\circ\ T\ \mathsf{A0}))))))
```

If we rename Ap1 to del; Ap1° to ins and AX to mod we see some familiar structure arising! Aligning products is the same as computing the diff between heterogeneous lists! In fact, the align function is defined as:

```
\begin{array}{lll} \operatorname{align}^* : \left\{ty \; tv : \Pi\right\} \to \left[\!\!\left[\; ty \;\right]\!\!\right]_p \to \left[\!\!\left[\; tv \;\right]\!\!\right]_p \to \operatorname{List}\left(\operatorname{Al} \Delta_a \; ty \; tv\right) \\ \operatorname{align}^* \left\{\left[\right]\right\} & m \; n = \operatorname{return} \operatorname{AO} \\ \operatorname{align}^* \left\{\left[\right]\right\} & \left\{v :: \; tv\right\} \; m \; (n \; , nn) \\ &= \operatorname{Ap1}^\circ \; n < \$ > \operatorname{align}^* \; m \; nn \\ \operatorname{align}^* \left\{y :: \; ty\right\} & \left\{\left[\right]\right\} & (m \; , mm) \; n \\ &= \operatorname{Ap1} \; m < \$ > \operatorname{align}^* \; mm \; n \\ \operatorname{align}^* \left\{y :: \; ty\right\} & \left\{v :: \; tv\right\} & (m \; , mm) \; (n \; , nn) \\ &= \operatorname{AX} \; (m \; , n) \; < \$ > \operatorname{align}^* \; mm \; nn \\ &+ + \operatorname{Ap1} \; m \; & \left\{\$ > \operatorname{filter}\left(\operatorname{not} \circ \operatorname{is-ap1}^\circ\right) \; \left(\operatorname{align}^* \; mm \; (n \; , nn)\right) \\ &+ + \operatorname{Ap1}^\circ \; n \; & \left\{\$ > \operatorname{filter}\left(\operatorname{not} \circ \operatorname{is-ap1}^\circ\right) \; \left(\operatorname{align}^* \; (m \; , mm) \; nn\right) \\ & \text{where} \\ & \operatorname{is-ap1} : \; \left\{ty \; tv : \; \Pi\right\} \to \operatorname{Al} \; \Delta_a \; ty \; tv \to \operatorname{Bool} \\ & \operatorname{is-ap1} \; \left(\operatorname{Ap1} \; \_ \right) = \operatorname{true} \\ & \operatorname{is-ap1}^\circ \; \left(\operatorname{Ap1}^\circ \; \_ \right) = \operatorname{true} \\ & \operatorname{is-ap1}^\circ \; \_ = \operatorname{false} \end{array}
```

We are now doing things in the *List* monad. This is needed because there are many possible alignments between two products. For the moment, we refrain from choosing and compute all of them.

On another note, some of these alignments are simply dumb! We do not want to have both Ap1 x (Ap1° y a) and AX (x, y) a. They are the same alignment. The filters are in charge of pruning out those branches from out search-space.

Sticking with our example, we can align the leaves of our c by computing the following expression, where  $\mathsf{C\text{-}map}\mathsf{M}$  is simply the monadic variant of  $\mathsf{C\text{-}map}\mathsf{M}$ .

```
\begin{split} a &= \mathsf{C-mapM \ align}^* \ c \\ &= \mathsf{SX} \ (\mathsf{CX} \ 2\mathsf{-node} \ 3\mathsf{-node} \ (\mathsf{AX} \ (10 \ , 10) \ (\mathsf{AX} \ (\mathsf{unit} \ , \mathsf{unit}) \ \cdots))) \\ &:: \mathsf{SX} \ (\mathsf{CX} \ 2\mathsf{-node} \ 3\mathsf{-node} \ (\mathsf{Ap1} \ 10 \ (\mathsf{AX} \ (\mathsf{unit} \ , 10) \ \cdots))) \\ &:: \mathsf{SX} \ (\mathsf{CX} \ 2\mathsf{-node} \ 3\mathsf{-node} \ (\mathsf{Ap1} \ 10 \ (\mathsf{Ap1} \ \mathsf{unit} \ \cdots))) \\ &:: \mathsf{SX} \ (\mathsf{CX} \ 2\mathsf{-node} \ 3\mathsf{-node} \ (\mathsf{Ap1} \ 10 \ (\mathsf{AX} \ (10 \ , \mathsf{unit}) \ \cdots))) \\ &\cdots \end{split}
```

Now we have a problem. Which of the patches above should we chose to be *the* patch? Recall that we mentioned we wanted to find the alignment with *maximum domain*. Something interesting happens if we look at patches from their "application" relation, but first, we define the "application" relations of Al:

$$(\mathsf{AX}\ a_1\ a_2)^{\flat} = \ B \times \Pi D \overset{a_1^{\flat} \times a_2^{\flat}}{\longleftarrow} A \times \Pi C$$

$$(\mathsf{Ap1}\ x\ a)^{\flat} = \qquad \Pi B \overset{\langle \underline{x}, a^{\flat^{\circ}} \rangle^{\circ}}{\longleftarrow} X \times \Pi A$$

$$(\mathsf{Ap1}^{\circ}\ x\ a)^{\flat} = \ X \times \Pi B \overset{\langle \underline{x}, a^{\flat} \rangle}{\longleftarrow} \Pi A$$

$$\mathsf{A0}^{\flat} = \qquad \mathbb{1} \overset{\mathsf{T}}{\longleftarrow} \mathbb{1}$$

### 3 Patches as Relations

In order to better illustrate this concept, we need a simpler example first. Let's consider the following type with no type variables:

$$\begin{array}{ll} \mathsf{Type1} &= \mathsf{K} \; \mathsf{k} \mathbb{N} \; \otimes \; [] \\ & \oplus \; \mathsf{K} \; \mathsf{k} \mathbb{N} \; \otimes \; \mathsf{K} \; \mathsf{k} \mathbb{N} \; \otimes \; [] \\ & \oplus \; [] \end{array}$$

It clearly has two constructors:

```
C_1 C_2 : Constr Type1 C_1 = fz C_2 = fs fz
```

Now, let's take two inhabitants of Type1.

```
\begin{array}{lll} x \; y \; : \; \llbracket \; \mathsf{Type1} \; \rrbracket \\ x & = \mathsf{inject} \; \mathsf{C}_2 \; (\mathsf{4} \; , \mathsf{10} \; , \; \mathsf{unit}) \\ y & = \mathsf{inject} \; \mathsf{C}_1 \; (\mathsf{10} \; , \; \mathsf{unit}) \end{array}
```

There are two possible options for diff x y:

Consider the semantics for  $\Delta$  as described in the discussion box at Section 2.1, that is,

$$(x, y)^{\flat} = \begin{cases} id & \text{if } x \equiv y \\ \underline{y} \cdot \underline{x}^{\circ} & \text{otherwise} \end{cases}$$

Then it becomes clear that we want to select patch (P2) instead of (P1). In fact, there is a deeper underlying reason for that! Looking at the two patches as relations (after some simplifications), we have:

$$P1^{\flat} = \operatorname{inj}_{\mathsf{C}_{1}} \cdot \langle (\underline{4} \cdot \underline{10}^{\circ}), \underline{10} \rangle^{\circ} \cdot \operatorname{inj}_{\mathsf{C}_{2}}^{\circ}$$

$$P2^{\flat} = \operatorname{inj}_{\mathsf{C}_{1}} \cdot \langle 4, id \rangle^{\circ} \cdot \operatorname{inj}_{\mathsf{C}_{2}}^{\circ}$$

Drawing them in a diagram we have:

Here, we have something curious going on... We have that  $P1^{\flat} \subseteq P2^{\flat}$ . To see this is not very hard. First, composition and converses are monotonous with respect to  $\subseteq$ . We are left to check that:

The first proof obligation is easy to calculate with:

```
\pi_{1} < \underline{4} \cdot \underline{10}^{\circ}, \underline{10} > \subseteq \underline{4}
\Leftarrow \{ \pi_{1}\text{-cancel} ; \subseteq \text{-trans} \}
\underline{4} \cdot \underline{10}^{\circ} \subseteq \underline{4}
\Leftarrow \{ \text{Leibniz} \}
\underline{4} \cdot \underline{10}^{\circ} \cdot \underline{10} \subseteq \underline{4} \cdot \underline{10}
\equiv \{ \underline{a}^{\circ} \cdot \underline{a} \equiv \top \}
\underline{4} \cdot \top \subseteq \underline{4} \cdot \underline{10}
\equiv \{ \underline{a} \cdot \underline{b} \equiv \underline{a} \}
\underline{4} \cdot \top \subseteq \underline{4}
\equiv \{ \underline{a} \cdot \top \equiv \underline{a} \}
\underline{4} \subseteq \underline{4}
\equiv \{ \subseteq \text{-refl} \}
True
```

The second is easier to prove once we add variables!

```
\pi_2 \cdot < 4 \cdot 10^{\circ}, 10 > \subseteq id
\equiv \{ \text{ Add variables } \}
        \forall x, y : x \ (\pi_2 \cdot < \underline{4} \cdot \underline{10}^\circ, \underline{10} >) \ y \Rightarrow x = y
\equiv \{ PF \text{ expand composition } \}
        \forall x, y . \exists z . x (\pi_2) z \land z < \underline{4} \cdot \underline{10}^{\circ}, \underline{10} > y \Rightarrow x = y
\equiv \{ \text{ Types force } z = (z_1, z_2) \}
        \forall x, y \ \exists z_1, z_2 \ x \ (\pi_2) \ (z_1, z_2) \land (z_1, z_2) \ < \underline{4} \cdot \underline{10}^{\circ}, \underline{10} > \ y \Rightarrow x = y
\equiv \{ \pi_2 \text{ def } \}
        \forall x, y \ \exists z_1, z_2 \ . \ x = z_2 \land (z_1, z_2) \ < \underline{4} \cdot \underline{10}^{\circ}, \underline{10} > \ y \Rightarrow x = y
\equiv \{ \text{ split def } \}
        \forall x, y . \exists z_1, z_2 . x = z_2 \land z_1 (\underline{4} \cdot \underline{10}^{\circ}) \ y \land z_2 (\underline{10}) \ y \Rightarrow x = y
\equiv \{ \text{ points def } \}
        \forall x, y . \exists z_1, z_2 . x = z_2 \land z_1 = 4 \land y = 10 \land z_2 = 10 \Rightarrow x = y
\equiv \{ \text{ substitutions ; weakening } \}
        \forall x, y . \exists z_2 . x = 10 \land y = 10 \Rightarrow x = y
\equiv \{ \text{ trivial } \}
        True
```

Nevertheless, it is clear which patch we should choose! We should always choose the patch that gives rise to the biggest relation, as this is applicable to much more elements.

Hence, our *cost* functions will count how many elements of the domain and range of the "application" relation of a patch are *fixed*. Note that the S and C parts of the algorithm are completely deterministic, hence they should *not* contribute to cost:

```
\begin{array}{l} \mathsf{S\text{-}cost} : \{ty: \, \mathsf{U}\}\{P: \, \mathsf{UUSet}\}(\mathit{doP}: \{k\,\,v: \, \mathsf{U}\} \to P\,\,k\,\,v \to \mathbb{N}) \\ \to \mathsf{S}\,\,P\,\,ty \to \mathbb{N} \\ \mathsf{S\text{-}cost}\,\,\mathit{doP}\,\,(\mathsf{SX}\,\,x) &= \mathit{doP}\,\,x \\ \mathsf{S\text{-}cost}\,\,\mathit{doP}\,\,\mathsf{Scp} &= 0 \\ \mathsf{S\text{-}cost}\,\,\mathit{doP}\,\,(\mathsf{Scns}\,\,i\,\,xs) &= \mathsf{foldr}_i\,\,(\lambda\,\,h\,\,r \to \mathit{doP}\,\,h + r)\,\,0\,\,xs \end{array}
```

```
 \begin{array}{ll} \mathsf{C\text{-}cost} & : \{\mathit{ty}\ \mathit{tv} : \, \mathsf{U}\}\{P : \Pi\Pi\mathsf{Set}\}(\mathit{doP} : \{\mathit{k}\ \mathit{v} : \, \Pi\} \to P\ \mathit{k}\ \mathit{v} \to \mathbb{N}) \\ & \to \mathsf{C}\ \mathit{P}\ \mathit{ty}\ \mathit{tv} \to \mathbb{N} \\ \mathsf{C\text{-}cost}\ \mathit{doP}\ (\mathsf{CX}\ \mathit{i}\ \mathit{j}\ \mathit{x}) = \mathit{doP}\ \mathit{x} \\ \end{array}
```

An Alignment might fix one element on the source, using Ap1 or one element on the destination, using Ap1°.

```
\begin{array}{l} \mathsf{Al\text{-}cost} : \{ty\ tv:\ \Pi\}\{P: \mathsf{AASet}\} (\mathit{doP}: \{k\ v:\ \mathsf{Atom}\} \to P\ k\ v \to \mathbb{N}) \\ \to \mathsf{Al}\ P\ ty\ tv \to \mathbb{N} \\ \mathsf{Al\text{-}cost}\ \mathit{doP}\ \mathsf{A0} &= 0 \\ \mathsf{Al\text{-}cost}\ \mathit{doP}\ (\mathsf{Ap1}\ x\ a) &= 1 + \mathsf{Al\text{-}cost}\ \mathit{doP}\ a \\ \mathsf{Al\text{-}cost}\ \mathit{doP}\ (\mathsf{Ap1}^\circ\ x\ a) &= 1 + \mathsf{Al\text{-}cost}\ \mathit{doP}\ a \\ \mathsf{Al\text{-}cost}\ \mathit{doP}\ (\mathsf{AX}\ x\ a) &= \mathit{doP}\ x + \mathsf{Al\text{-}cost}\ \mathit{doP}\ a \\ \end{array}
```

Last but not least, a  $\Delta$  will either fix 2 elements: one in the source that becomes one in the destination; or none, when we just copy the source.

```
\begin{array}{l} \operatorname{cost-delta-raw}: \ \mathbb{N} \\ \operatorname{cost-delta-raw} = 2 \\ \\ \operatorname{cost-delta}: \ \forall \{\alpha\} \{A: \operatorname{Set} \ \alpha\} \{ty \ tv: \ A\} (P: A \to \operatorname{Set}) \\ (eqA: (x \ y: A) \to \operatorname{Dec} \ (x \equiv y)) \\ (eqP: (k: A)(x \ y: P \ k) \to \operatorname{Dec} \ (x \equiv y)) \\ \to \operatorname{delta} \ P \ ty \ tv \to \mathbb{N} \\ \operatorname{cost-delta} \ \{ty = ty\} \ \{tv = tv\} \ P \ eqA \ eqP \ (pa1 \ , pa2) \\ \text{with} \ eqA \ ty \ tv \\ \dots | \ \operatorname{no} \ \_ = \operatorname{cost-delta-raw} \\ \operatorname{cost-delta} \ \{ty = ty\} \ P \ eqA \ eqP \ (pa1 \ , pa2) \\ | \ \operatorname{yes} \ refl \ with} \ eqP \ ty \ pa1 \ pa2 \\ \dots | \ \operatorname{no} \ \_ = \operatorname{cost-delta-raw} \\ \dots | \ \operatorname{no} \ \_ = \operatorname{cost-delta-raw} \\ \dots | \ \operatorname{no} \ \_ = \operatorname{cost-delta-raw} \\ \dots | \ \operatorname{yes} \ \_ = 0 \\ \end{array}
```

According to these definitions, the cost of (P1) above is 3, where the cost of (P2) is 1.

#### 3.1 Patches for Regular Types

Now that we have *spines*, *changes* and *alignments* figured out, we can define a patch as:

```
Patch : AASet \rightarrow U \rightarrow Set Patch P = S (C (AI P))
```

Computing inhabitants of such type is done with:

```
\mathsf{diff1*}: \{ty: \mathsf{U}\}(x\ y: \llbracket\ ty\ \rrbracket) \to \mathsf{Patch*}\ ty \mathsf{diff1*}\ x\ y = \mathsf{S-mapM}\ (\mathsf{C-mapM}\ (\mathsf{uncurry\ align*}) \circ \mathsf{uncurry\ change})\ (\mathsf{spine}\ x\ y)
```

where Patch\* is defined as List (Patch  $\Delta_a$ ).

#### 3.2 Conjectures About the cost function

Here we conjecture a few lemmas about the interplay of the cost function and the "application" relation. Let P, Q and R be patches.

i) If P has a lower cost than Q, then the domain and range of the "application" relation of P contains the "application" relation of Q.

$$\mathsf{cost}\ P < \mathsf{cost}\ Q\ \Rightarrow\ Q^{\flat}\ \subset\ P^{\flat}\ \cdot\ \top\ \cdot\ P^{\flat}$$

#### Needs discussion:

This is not as simple as

$$\cos P < \cos Q \implies Q^{\flat} \subseteq P^{\flat}$$

Take two *Deltas*, px=(10,50) and py=(30,30). Trivially, cost py=0 and cost px=2. Now,  $px^{\flat}=\underline{50}\cdot\underline{10}^{\circ}$  and  $py^{\flat}=id$ . It is not true that  $50\cdot10^{\circ}\subseteq id$ !

not true that  $\underline{50} \cdot \underline{10}^{\circ} \subseteq id!$  If we state, however: Let P, Q in diff \* x y; cost  $P < \cos Q \Rightarrow Q^{\flat} \subseteq P^{\flat}$  Seems more likely. As the above counter example would not work anymore.  $diff * 10 \ 50 = (10 \ , 50) ::[].$ 

ii) If P and Q have equal cost, it means that there is at least one place where P and Q are doing the same thing, hence there is a patch that copies this same thing and costs strictly less.

$$\mathsf{cost}\ P\ \equiv\ \mathsf{cost}\ Q\ \Rightarrow\ \exists\ R\ \cdot\ \mathsf{cost}\ R<\mathsf{cost}\ P$$

# 4 Mutually Recursive Types

Now that we have a clear picture of regular types, extending this to recursive types is not very difficult.

First, recall that a mutually recursive family is defined as n codes that each reference n type variables:

Another auxiliary definition we use here is the indexed coproduct, which let's us *extend* some indexed type.

$$\_+_u\_: \{n: \mathbb{N}\} \to (\sigma\pi\ n \to \sigma\pi\ n \to \mathsf{Set}) \to (\sigma\pi\ n \to \sigma\pi\ n \to \mathsf{Set})$$

Now, we already have the ingredients for detecting and representing common constructors or full copies, with S, constructor changes, with C and alignments with Al. We just need to handle type variables to tie the knot. Before we proceed with the nasty definitions, we still need two last synonyms:

```
\mathsf{Fam}_i: \mathsf{Set} \mathsf{Fam}_i = \mathsf{Fin} \ fam\# \mathsf{T}: \mathsf{Fam}_i 	o \sigma\pi \ fam\# \mathsf{T} \ k = \mathsf{lookup} \ k \ fam
```

Here T k represents the k-th type of the family, and  $\mathsf{Fam}_i$  acts a the the types in the family.

We start defining a patch for fixed poins by allowing normal patches to perform changes on the first layer.

```
\begin{array}{l} \mathsf{data} \; \mathsf{Patch} \mu : \; \mathsf{U} \to \mathsf{U} \to \mathsf{Set} \; \mathsf{where} \\ \mathsf{skel} \; : \; \{ty : \; \mathsf{U}\} \to \mathsf{Patch} \; (\mathsf{UU} \to \mathsf{AA} \; \mathsf{Patch} \mu) \; ty \\ \to \; \mathsf{Patch} \mu \; ty \; ty \end{array}
```

However, a patch for a fixed point might not only follow the precise order of operations (S, then C, then Al) that regular types enjoyed. For instance, imagine we are transforming the following lists:

```
[5, 8, 13, 21] \rightsquigarrow [8, 13, 21]
```

Let lists be seen (as usual) as the initial algebras of  $L_A$   $X = 1 + A \times X$ ; then, both lists are inhabitants of  $\mu L_N$ , but, more precisely, the source is an inhabitant of  $L_N(L_N(L_N(L_N \mathbb{1})))$  whereas the target is an inhabitant of  $L_N(L_N(L_N \mathbb{1}))$ .

Here, we are already beginning with different types, so a spine (which is homogeneous) might not be the best start! In fact, the best start is to say that the first 5 is deleted, then the spine can kick in and say that everything else is copied!

Deleting and inserting can be seen as alignments between a type variable and the type we wish to delete or insert. For instance, deleting 5, which is actually 5:, consists in deleting the \_::\_ constructor and aligning the  $\mathbb{N} \times |k|$  with with a type variable |k|. Insertions are analogous.

```
\begin{array}{ll} \text{ins} & : \{ty: \, \mathsf{U}\}\{k: \, \mathsf{Fam}_i\}(i: \, \mathsf{Constr} \, ty) \\ & \to \mathsf{Al} \, (\mathsf{UU} \! \to \! \mathsf{AA} \, \mathsf{Patch} \mu) \, \left( \mathsf{I} \, k :: \, [] \right) \, (\mathsf{typeOf} \, ty \, i) \\ & \to \mathsf{Patch} \mu \, \left( \mathsf{T} \, k \right) \, ty \\ \mathsf{del} & : \{ty: \, \mathsf{U}\}\{k: \, \mathsf{Fam}_i\}(i: \, \mathsf{Constr} \, ty) \\ & \to \mathsf{Al} \, \left( \mathsf{UU} \! \to \! \mathsf{AA} \, \, \mathsf{Patch} \mu \right) \, (\mathsf{typeOf} \, ty \, i) \, \left( \mathsf{I} \, k :: \, [] \right) \\ & \to \mathsf{Patch} \mu \, ty \, \left( \mathsf{T} \, \, k \right) \end{array}
```

Note, however, that we use  $UU \to AA$  Patch $\mu$  to populate the leaves of Patch and Al. That's because their parameter is of type  $Atom \to Atom \to Set$ , but Patch $\mu$  has type  $U \to U \to Set$ . Nevertheless, when these leaves are just two type variables, we want to keep using Patch $\mu$  to record their differences. When these leaves are constant types, we give up and set their values with a delta.

```
\begin{array}{ll} \text{fix} & : \; \{k\;k'\; : \; \mathsf{Fam}_i\} \\ & \to \mathsf{Patch}\mu \; (\mathsf{T}\;k) \; (\mathsf{T}\;k') \\ & \to \mathsf{Patch}\mu \; (\alpha \; (\mathsf{I}\;k)) \; (\alpha \; (\mathsf{I}\;k')) \\ \text{set} & : \; \{ty\;tv:\; \mathsf{U}\} \\ & \to \Delta_s \; ty\;tv \\ & \to \mathsf{Patch}\mu \; ty\;tv \end{array}
```

Associating costs are trivial. We just piggy back on the previous cost definitions. I am still very puzzled for how this works.

Nevertheless, the heart of the algorithm is the same as any patching algorithm out there. Things can be modified, inserted or deleted:

Modifying must happen at the same type only, otherwise we force an insertion or deletion. If we are, in fact, on the same type, we can get the patch for that layer and continue diffing atoms.

```
\begin{array}{l} \operatorname{diff}\mu^*\operatorname{-mod}: \{ty\ tv:\ \mathsf{U}\}\to \llbracket\ ty\ \rrbracket\to \llbracket\ tv\ \rrbracket\to \operatorname{List}\ (\operatorname{Patch}\mu\ ty\ tv)\\ \operatorname{diff}\mu^*\operatorname{-mod}\ \{ty\}\ \{tv\}\ x\ y\ \operatorname{with}\ \sigma\pi\operatorname{-eq}\ ty\ tv\\ \ldots\mid \operatorname{no}\ \_=[]\\ \operatorname{diff}\mu^*\operatorname{-mod}\ x\ y\\ \mid \operatorname{yes}\ \operatorname{refl}\\ =\operatorname{skel}<\$> (\operatorname{diff}1^*\ x\ y\ \operatorname{"}=\operatorname{Patch-mapM}\ (\operatorname{uncurry}\ \operatorname{diff}\mu^*\operatorname{-atoms})) \end{array}
```

Atoms are easy to diff. If reach two type variables, we tie the knot and keep patching. If we reach two constants, we set one into the other. Any other situation is forbiden.

Insertions and deletions are very simple:

```
\begin{array}{l} \operatorname{diff}\mu^*\text{-}\operatorname{ins}: \{ty: \mathsf{U}\}\{k: \mathsf{Fam}_i\} \to \mathsf{Fix} \ fam \ k \to \llbracket \ ty \ \rrbracket \to \mathsf{List} \ (\mathsf{Patch}\mu \ (\mathsf{T} \ k) \ ty) \\ \operatorname{diff}\mu^*\text{-}\operatorname{ins} \ x \ y \ \text{with} \ \operatorname{sop} \ y \\ \operatorname{diff}\mu^*\text{-}\operatorname{ins} \ x \ \_ \ | \ \operatorname{strip} \ cy \ dy \\ = \operatorname{ins} \ cy <\$ > \operatorname{align}\mu' \ (x \ , \ \operatorname{unit}) \ dy \end{array}
```

```
\begin{array}{l} \operatorname{diff}\mu^*\text{-del}: \{ty: \mathsf{U}\}\{k: \mathsf{Fam}_i\} \to \llbracket \ ty \ \rrbracket \to \mathsf{Fix} \ fam \ k \to \mathsf{List} \ (\mathsf{Patch}\mu \ ty \ (\mathsf{T} \ k)) \\ \operatorname{diff}\mu^*\text{-del} \ x \ y \ \mathsf{with} \ \mathsf{sop} \ x \\ \operatorname{diff}\mu^*\text{-del} \ \ y \ | \ \mathsf{strip} \ cx \ dx \\ = \operatorname{del} \ cx < > \ \mathsf{align}\mu' \ dx \ (y \ , \ \mathsf{unit}) \end{array}
```

We just need to pay attention not to insert or delete some constructor without arguments; This is done on the auxiliar alignment function:

```
\begin{array}{lll} \operatorname{align} \mu' &: \{ ty \ tv : \Pi \} \to \llbracket \ ty \ \rrbracket_p \to \llbracket \ tv \ \rrbracket_p \\ &\to \operatorname{List} \ (\operatorname{Al} \ (\operatorname{UU} \to \operatorname{AA} \ \operatorname{Patch} \mu) \ ty \ tv) \\ \operatorname{align} \mu' \left\{ \llbracket \right\} & \left\{ \_ \right\} & = \llbracket \rrbracket \\ \operatorname{align} \mu' \left\{ \_ \right\} & \left\{ \llbracket \right\} & \_ \_ = \llbracket \rrbracket \\ \operatorname{align} \mu' \left\{ \_ :: \_ \right\} & \left\{ \_ :: \_ \right\} \ x \ y & = \operatorname{align} \mu \ x \ y \end{array}
```

Which ignores empty products. If we are not aligning empty products, we can just piggyback on the previous alignment function we had:

```
\begin{array}{ll} \mathsf{align} \mu &: \{ty \ tv : \Pi\} \to [\![ty \ ]\!]_p \to [\![tv \ ]\!]_p \\ &\to \mathsf{List} \ (\mathsf{Al} \ (\mathsf{UU} \to \mathsf{AA} \ \mathsf{Patch} \mu) \ ty \ tv) \\ \mathsf{align} \mu \ x \ y \ \mathsf{=} \ \mathsf{align}^* \ x \ y \ \mathsf{>} = \mathsf{Al-mapM} \ (\mathsf{uncurry} \ \mathsf{diff} \mu^*\!\!-\!\!\mathsf{atoms}) \end{array}
```

Now we just need to choose the patch with the least cost for the deterministic version.

```
\begin{array}{l} \operatorname{diff} \mu : \{k \; k' : \mathsf{Fam}_i\} \to \mathsf{Fix} \; fam \; k \to \mathsf{Fix} \; fam \; k' \to \mathsf{Patch} \mu \; (\mathsf{T} \; k') \\ \operatorname{diff} \mu \; \{k\} \; x \; y \; \text{with} \; \operatorname{diff} \mu^* \; x \; y \\ \ldots \mid s :: \; ss \; = s < \mu > ss \\ \ldots \mid [] \qquad \qquad = \mathsf{set} \; (\mathsf{unmu} \; x \; , \; \mathsf{unmu} \; y) \end{array}
```

# Needs discussion:

If we define a family of two types, say K  $\mathbb{N}$ ::K Bool::[]. Now take  $x=\mathsf{inject}$  fz 10 and  $y=\mathsf{inject}$  (fs fz) true.

Here, diffmu\* x y = []. It is easy to see why. We can't modify because we have two different types. We can't insert or delete because both inhabitants were constructed with constructors that have no recursive arguments.

In a real scenario, though, this will never happen. Mainly because we are only interested in diffing things of the same type. Sure, the types might change during the algorithm, but they start the same; hence at least a modify is always possible.

On another note; The aforementioned type family is not really a type family, but a single type:  $\mathbb{N} + \mathbb{B}$ .

Obviously, we can also define the "application" relation for fixed points, and that is done in RegDiff/Diff/Multirec/Domain. I believe it is more worthwhile to look at some example patches and their "application" relation instead of the general case, though. Let's begin with the lists we just discussed:

```
s0 : Patch\mu LIST-F LIST-F s0 = diff\mu (5 > 8 > 13 > 21 > #) (8 > 13 > 21 > #) s0-norm : Patch\mu LIST-F LIST-F s0-norm = del cons' (Ap1 5 (AX (fix (skel Scp)) A0))
```

Here, LIST-F is defined as  $u1 \oplus \mathbb{N} \otimes I$ , the usual list functor. The "application" relation for the above patch is (isomorphic to):

$$\begin{array}{c|c} 1 + \mathbb{N} \times [\mathbb{N}] & \xrightarrow{\mathfrak{s0}} & 1 + \mathbb{N} \times [\mathbb{N}] \\ & \iota_{2}^{\circ} \middle| & & & \text{in}^{\circ} \middle| \\ \mathbb{N} \times [\mathbb{N}] & \xrightarrow{\mathfrak{5}^{\circ} \times id} & \mathbb{N} \times [\mathbb{N}] & \xrightarrow{\pi_{2}} & [\mathbb{N}] \end{array}$$

# 4.1 Examples

Here we add some more examples of patches over fixpoints. These can be seen in the respective Lab.agda modules. Here are a few examples of list patches:

```
10 l1 : list
10 = (3 > 50 > 4 > \#)

11 = (1 > 50 > 4 > 20 > \#)
s1: \mathsf{Patch}\mu \ \mathsf{LIST}	ext{-}\mathsf{F} \ \mathsf{LIST}	ext{-}\mathsf{F}
s1 = diff \mu l0 l1
s1-normalized : Patch\mu LIST-F LIST-F
s1-normalized
    = skel
        (Scns cons'
            (CX fz fz (AX (set (\rightarrow \alpha \ 3 \ , \rightarrow \alpha \ 1)) A0) ::
                (CX fz fz
                    (AX
                         (fix
                            (skel
                                 (Scns cons'
                                     (CX fz fz (AX (set (\rightarrow \alpha 50 , \rightarrow \alpha 50)) A0) ::
                                         (CX fz fz
                                             (AX
                                                 (fix
                                                      (skel
                                                          (Scns cons'
                                                              (CX fz fz (AX (set (\rightarrow \alpha \ 4 \ , \rightarrow \alpha \ 4)) A0) ::
                                                                  (CX fz fz
                                                                      (AX (fix (ins cons' (Ap1° 20 (AX (fix (skel Scp)) A0)))) A0)
                                                                      :: [])))))
                                                 A0)
                                             :: [])))))
                         A0)
                     :: [])))
```

Previously we had 2-3-Trees as an example. Here are some patches over them:

```
import RegDiff.Diff.Multirec.Base konstants keqs
    as DIFF
open DIFF.Internal (2-3-TREE-F :: []) public

k0 k1 k2 : 2-3-Tree
k0 = Leaf
k1 = 2-Node 1 Leaf Leaf
k2 = 3-Node 5 Leaf Leaf Leaf
k3 = 3-Node 3 k1 k2 k2

t1 t2 : 2-3-Tree
t1 = 2-Node 4 k1 k2
t2 = 3-Node 5 k1 Leaf k2
```

The patches we calculate are:

```
r1 r2 : Patch\mu 2-3-TREE-F 2-3-TREE-F r1 = diff\mu t1 t2 r2 = diff\mu k1 k3
```

Which are normalized to the following patches. Note that it is the  $A \otimes$  in r1 that lets us copy k1 and k2 from the 2-node to the 3-node.

```
r1-normalized : Patch\mu 2-3-TREE-F 2-3-TREE-F
r1-normalized
   = skel
       (SX
          (CX 2-node' 3-node'
              (AX (set (i1 (4 , unit) , i1 (5 , unit)))
                  (AX (fix (skel Scp))
                     (Ap1° ( i1 unit ) (AX (fix (skel Scp)) A0))))))
r2-normalized : Patch\mu 2-3-TREE-F 2-3-TREE-F
r2-normalized
   = ins 3-node
       (Ap1° 3
           (AX (fix (skel Scp))
                  \langle i2 (i2 (i1 (5 , \langle i1 unit \rangle , \langle i1 unit \rangle , \langle i1 unit \rangle , unit)))
                  (Ap1^{\circ}
                     \langle i2 (i2 (i1 (5 , \langle i1 unit \rangle , \langle i1 unit \rangle , \langle i1 unit \rangle , unit)))
                     A0))))
```

# 5 Comparing to the Rose Tree approach

# Needs discussion:

- $\bullet$  By using a list of edit operations, they lose the alignments.
- They allow for sharing of data even when the same constructor is used.
